Code is clean if it can be understood easily - by everyone on the team. With understandability comes readability, changeability, extensibility and maintainability. All the things needed to keep a project going over a long time without accumulating up a large amount of technical debt.

Writing clean code from the start in a project is an investment in keeping the cost of change as constant as possible throughout the lifecycle of a software product. Therefore, the initial cost of change is a bit higher when writing clean code (grey line) than guick and dirty programming (black line), but is paid back quite soon. Especially if you keep in mind that most of the cost has to be paid during maintenance of the software. Unclean code results in technical debt that increases over time if not refactored into clear code. There are other reasons leading to Technical Debt such as bad processes and lack of documentation, but unclean code is a major driver. As a result, your ability to respond to changes is reduced (red line).

In Clean Code, Bugs Cannot Hide

Most software defects are introduced when changing existing code. The reason behind this is that the developer changing the code cannot fully grasp the effects of the changes made. Clean code minimises the risk of introducing defects by making the code as easy to understand as possible.

Loose Coupling

()

ന

Two classes, components or modules are coupled when at least one of them uses the other. The less these items know about each other, the ooser they are coupled.

A component that is only loosely coupled to its environment can be more easily changed or replaced than a strongly coupled component.

High Cohesion

Cohesion is the degree to which elements of a whole belong together. Methods and fields in a single class and classes of a component should have high cohesion. High cohesion in classes and components results in simpler, more easily understandable code structure and design.

Change is Local

When a software system has to be maintained, extended and changed for a long time, keeping change local reduces involved costs and risks. Keeping change local means that there are boundaries in the design which changes do not cross.

It is Easy to Remove

We normally build software by adding, extending or changing features. However, removing elements is important so that the overall design can be kept as simple as possible. When a block gets too complicated, it has to be removed and replaced with one or more simpler blocks.

Legend:	
DO	+
DON'T	—

	ls	el	m	S
--	----	----	---	---

Rigidity The software is difficult to change. A small change causes a cascade of subsequent changes.

Fragility The software breaks in many places due to a single change. Immobility

You cannot reuse parts of the code in other projects because of involved risks and high effort.

Viscosity of Design

Taking a shortcut and introducing technical debt requires less effort than doing it right.

Viscosity of Environment

Building, testing and other tasks take a long time. Therefore, these activities are not executed properly by everyone and technical debt is introduced.

Needless Complexity

The design contains elements that are currently not useful. The added complexity makes the code harder to comprehend. Therefore, extending and changing the code results in higher effort than necessary.

Needless Repetition

Code contains lots of code duplication: exact code duplications or design duplicates (doing the same thing in a different way). Making a change to a duplicated piece of code is more expensive and more error-prone because the change has to be made in several places with the risk that one place is not changed accordingly.

Opacity

The code is hard to understand. Therefore, any change takes additional time to first reengineer the code and is more likely to result in defects due to not understanding the side effects.

Single Responsibility Principle (SRP)

A class should have one, and only one, reason to change. Open Closed Principle (OCP) You should be able to extend a classes behaviour without modifying it. Liskov Substitution Principle (LSP) Derived classes must be substitutable for their base classes Dependency Inversion Principle (DIP) Depend on abstractions, not on concretions. Interface Segregation Principle (ISP) Make fine grained interfaces that are client-specific. Classes Should be Small Smaller classes are easier to grasp. Classes should be smaller than about 100 lines of code. Otherwise, it is hard to spot how the class does its job and it probably does more than a single job. Release Reuse Equivalency Principle (RREP) The granule of reuse is the granule of release. Common Closure Principle (CCP) Classes that change together are packaged together. Common Reuse Principle (CRP) Classes that are used together are packaged together.

Package Coupling

Acyclic Dependencies Principle (ADP) The dependency graph of packages must have no cycles. Stable Dependencies Principle (SDP) Depend in the direction of stability. Stable Abstractions Principle (SAP) Abstractness increases with stability

Follow Standard Conventions Coding-, architecture-, design guidelines (check them with tools) Keep it Simple, Stupid (KISS)

Simpler is always better. Reduce complexity as much as possible. Boy Scout Rule Leave the campground cleaner than you found it.

Root Cause Analysis

Always look for the root cause of a problem. Otherwise, it will get you again and again.

Multiple Languages in One Source File C#, Java, JavaScript, XML, HTML, XAML, English, German ...

Project Build Requires Only One Step Check out and then build with a single command.

Executing Tests Requires Only One Step Run all unit tests with a single command.

Source Control System

Always use a source control system.

Continuous Integration

Assure integrity with Continuous Integration

Overridden Safeties

Do not override warnings, errors, exception handling - they will catch you.

Dependency Injection

Decouple Construction from Runtime Decoupling the construction phase completely from the runtime helps to simplify the runtime behaviour.

Keep Configurable Data at High Levels If you have a constant such as default or configuration value that is known and expected at a high level of abstraction, do not bury it in a low-level function. Expose it as an argument to the low-level function called from the high-level function.

Don't Be Arbitrary

Have a reason for the way you structure your code, and make sure that reason is communicated by the structure of the code. If a structure appears arbitrary, others will feel empowered to change it.

Be Precise

When you make a decision in your code, make sure you make it precisely. Know why you have made it and how you will deal with any exceptions.

Structure over Convention

Enforce design decisions with structure over convention. Naming conventions are good, but they are inferior to structures that force compliance

Prefer Polymorphism To If/Else or Switch/Case

"ONE SWITCH": There may be no more than one switch statement for a given type of selection. The cases in that switch statement must create polymorphic objects that take the place of other such switch statements in the rest of the system.

Symmetry / Analogy

Favour symmetric designs (e.g. Load - Save) and designs that follow analogies (e.g. same design as found in .NET framework)

Separate Multi-Threading Code Do not mix code that handles multi-threading aspects with the rest of the code. Separate them into different classes.

Misplaced Responsibility Something put in the wrong place.

Code at Wrong Level of Abstraction Functionality is at wrong level of abstraction, e.g. a PercentageFull property on a generic IStack<T>.

Fields holding data that does not belong to the state of the instance but are used to hold temporary data. Use local variables or extract to a class abstracting the performed action. Over Configurability Prevent configuration just for the sake of it - or because nobody can decide how it should be. Otherwise, this will result in overly complex, unstable systems. Micro Layers Do not add functionality on top, but simplify overall Make Logical Dependencies Physical If one module depends upon another, that dependency should be physical, not just logical. Don't make assumptions. Singletons / Service Locator Use dependency injection. Singletons hide dependencies. Base Classes Depending On Their Derivatives Base classes should work with any derived class. Too Much Information Minimise interface to minimise coupling Feature Envy The methods of a class should be interested in the variables and functions of the class they belong to, and not the variables and functions of other classes. When a method uses accessors and mutators of some other object to manipulate the data within that object, then it envies the scope of the class of that other object. It wishes that it were inside that other class so that it could have direct access to the variables it is manipulating. Artificial Coupling Things that don't depend upon each other should not be artificially coupled Hidden Temporal Coupling

If, for example, the order of some method calls is important, then make sure that they cannot be called in the wrong order.

Transitive Navigation

Fields Not Defining State

+

Aka Law of Demeter, writing shy code. A module should know only its direct dependencies.

Choose Descriptive / Unambiguous Names Names have to reflect what a variable, field, property stands for. Names have to be precise Choose Names at Appropriate Level of Abstraction Choose names that reflect the level of abstraction of the class or method you are working in. Name Interfaces After Functionality They Abstract The name of an interface should be derived from its usage by the client, such as IStream. Name Classes After How They Implement Their Interfaces The name of a class should reflect how it fulfils the functionality provided by its interface(s), such as MemoryStream : IStream Name Methods After What They Do The name of a method should describe what is done, not how it is done. Use Long Names for Long Scopes fields → parameters → locals → loop variables long \rightarrow short Names Describe Side Effects Names have to reflect the entire functionality Standard Nomenclature Where Possible Don't invent your own language when there is a standard.

Test Not Belonging in Host Test Fixture

A test that tests a completely different testee than all other tests in the fixture.	
Obsolete Test	-

A test that checks something no longer required in the system. May even prevent clean-up of production code because it is still referenced.

Hidden Test Functionality

Test functionality hidden in either the SetUp method, base class or helper class. The test should be clear by looking at the test method only - no initialisation or asserts somewhere else.

Bloated Construction

The construction of dependencies and arguments used in calls to testee makes test hardly readable. Extract to helper methods that can be reused.

Unclear Fail Reason Split test or use assertion messages.

Conditional Test Logic

Tests should not have any conditional test logic because it's hard to read.

Test Logic in Production Code

Tests depend on special logic in production code.

Erratic Test Sometimes passes, sometimes fails due to left overs or environment.

A Test Checks One Feature

A test checks exactly one feature of the testee. That means that it tests all things included in this feature but not more. This includes probably more than one call to the testee. This way, the tests serve as samples and documentation of the usage of the testee.

Tiny Steps

Make tiny little steps. Add only a little code in test before writing the required production code. Then repeat. Add only one Assert per step.

Keep Tests Simple

Whenever a test gets complicated, check whether you can split the testee into several classes (Single Responsibility Principle)

Prefer State Verification to Behaviour Verification Use behaviour verification only if there is no state to verify.

Test Domain Specific Language Use test DSLs to simplify reading tests: helper methods, classes.

TDD Process Smells

Using Code Coverage as a Goal

Use code coverage to find missing tests but don't use it as a driving tool. Otherwise, the result could be tests that increase code coverage but not certainty

No Green Bar in the last ~10 Minutes

Make small steps to get feedback as fast and frequent as possible.

Not Running Test Before Writing Production Code Only if the test fails, then new code is required. Additionally, if the test, surprisingly, does not, fail then make sure the test is correct.

Not Spending Enough Time on Refactoring Refactoring is an investment in the future. Readability, changeability and

extensibility will pay back.

Skipping Something Too Easy to Test

Don't assume, check it. If it is easy, then the test is even easier.

Skipping Something Too Hard to Test

Make it simpler, otherwise bugs will hide in there and maintainability will suffer

Organising Tests around Methods, Not Behaviour

These tests are brittle and refactoring killers. Test complete "mini" use cases in a way which reflects how the feature will be used in the real world. Do not test setters and getters in isolation, test the scenario they are used in

One Step Test Pick a test you are confident you can implement and which maximises learning effect (e.g. impact on design).

Partial Test Write a test that does not fully check the required behaviour, but brings you a step closer to it. Then use Extend Test below.

Extend Test

Extend an existing test to better match real-world scenarios.

Another Test

If you think of new tests, then write them on the TO DO list and don't lose focus on current test.

Learning Test Write tests against external components to make sure they behave as expected.

Fake It ('Til You Make It) Return a constant to get first test running. Refactor later.

Triangulate – Drive Abstraction

Write test with at least two sets of sample data. Abstract implementation on these.

Obvious Implementation

If the implementation is obvious then just implement it and see if test runs. If not, then step back and just get test running and refactor then.

One to Many – Drive Collection Operations First, implement operation for a single element. Then, step to several elements.

Use Acceptance Tests to Drive Your TDD tests Acceptance tests check for the required functionality. Let them guide your TDD

User Feature Test

An acceptance test is a test for a complete user feature from top to bottom that provides business value.

Automated ATDD

Use automated Acceptance Test Driven Development for regression testing and executable specifications.

Component Acceptance Tests

Write acceptance tests for individual components or subsystems so that these parts can be combined freely without losing test coverage.

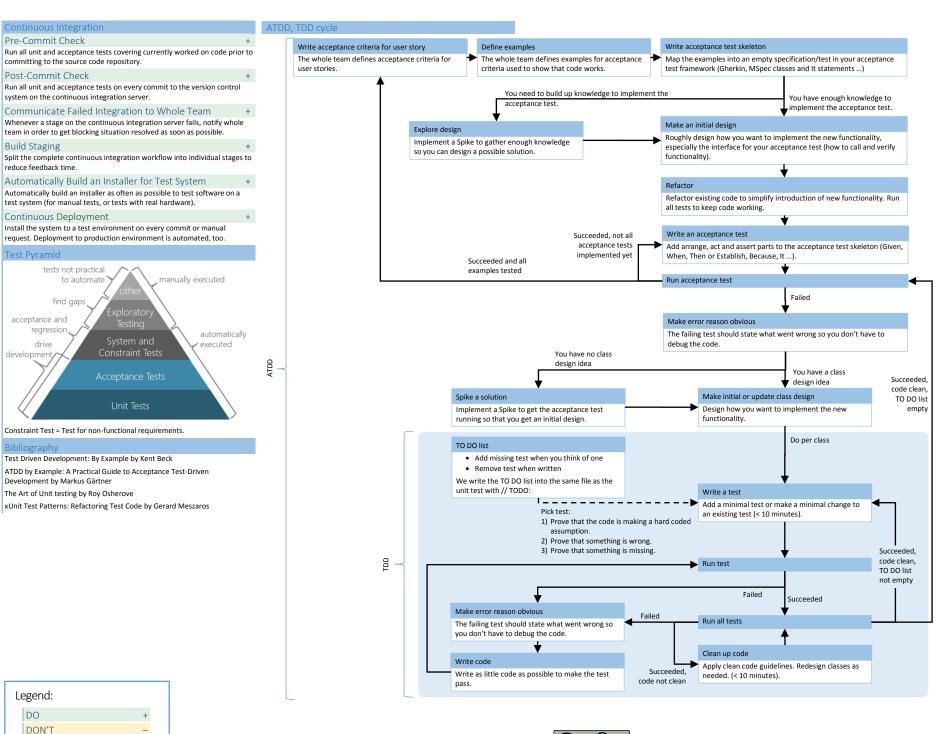

Simulate System Boundaries

Simulate system boundaries like the user interface, databases, file system and external services to speed up your acceptance tests and to be able to check exceptional cases (e.g. a full hard disk). Use system tests to check the boundaries.

Acceptance Test Spree

Do not write acceptance tests for every possibility. Write acceptance tests only for real scenarios. The exceptional and theoretical cases can be covered more easily with unit tests.
